

Conclusion

In conclusion, this project successfully demonstrates the implementation of a secure and efficient role-based user, group, and access control management system in ServiceNow. By defining distinct roles for the Project Manager and Team Member, the system ensures that each user has access only to the functions and data relevant to their responsibilities. This controlled access enhances security, accountability, and proper governance throughout the project lifecycle.

The use of Access Control Lists (ACLs) effectively restricts unauthorized actions while protecting sensitive project and task information. At the same time, the implementation of workflows and automation streamlines task assignment, progress tracking, status updates, and approval processes, reducing manual effort and improving operational efficiency.

Overall, the project establishes a scalable and well-governed ServiceNow environment that supports secure project management, clear accountability, and efficient collaboration within the project team. By combining role-based access control with workflow automation, the solution improves productivity, minimizes errors, and ensures that project activities are carried out in a consistent and controlled manner.
